If you were to measure the volume output of the BDDMEX, you will most likely notice a problem with the batteries. At higher power levels the DAC will not give a stable voltage output and your measurement would be unreliable.

---

There is a voltage droop, so before you measure it, you would need to change the batteries to get a stable measurement. When you see the droop, reduce the voltage level of the output (put in a 1K resistor, say between the battery and output) until the droop is completely gone. The NI/Labtec DAC comes with a very stable 9 volt regulated power supply, if you use it, you do not need to worry about running into any problems. You can change the power of the DAC when running, the LDAC gives you a very stable output with limited dynamic range. There are some very specific conditions when the DAC is not stable, the internal capacitor in the chip becomes unstable when it gets very hot and this is most likely what is happening in your case. You should be able to measure the output voltage and get around 20 mV, if not, you will most likely need to measure the voltage and power in the DAC, if you have an oscilloscope. A resistor between the battery and DAC board can help stabilize the output voltage of the LDAC. 82157476af
